# Counting Sample Points

- ❑ In many cases, we shall be able to solve a probability problem by counting the number of points in the **sample space without actually listing each element**.
- ❑ The **fundamental principle of counting**, often referred to as the **multiplication rule**, is stated in Rule 2.1.

**Rule 2.1:** If an operation can be performed in  $n_1$  ways, and if for **each of these ways a second operation** can be performed in  $n_2$  ways, then **the two operations** can be performed together in  $n_1 n_2$  ways.

□ **Example** : How many **sample points** are there in the **sample space** when a **pair of dice** is thrown once?

## Solution :

□ The first die gives us,  $n_1 = 6$  ways.

□ For each of these **6 ways**, the **second die** gives us,  $n_2 = 6$  ways.

□ Therefore, the pair of dice give us  $n_1 n_2 = (6)(6) = 36$  possible ways.

**Example :** If a **22-member club** needs to elect a **chair** and a **treasurer**, how many **different ways** can these **two** to be elected?

## Solution :

□ For the **chair position**, we have  $n_1 = 22$  ways

□ For the **treasurer** position, for each of those **21 possibilities**, we have  $n_2 = 21$  ways

□ Total number of ways =  $n_1 \times n_2 = 22 \times 21 = 462$

□ **Rule 2.2:** If an operation can be performed in  $n_1$  ways, and **if for each of these a second operation** can be performed in  $n_2$  ways, and for each of the **first two a third operation** can be performed in  $n_3$  ways, and so forth, then the sequence of  $k$  operations can be performed in  $n_1 n_2 \cdots n_k$  ways.

□ **Example:** Sam is going to assemble a computer by himself. He has the choice of chips from **two brands**, a **hard drive** from **four**, **memory** from **three**, and an **accessory bundle** from **five** local stores. How many **different ways** can Sam order the parts?

## **Solution :**

$$n_1 = 2 \text{ (No of brands)}$$

$$n_2 = 4 \text{ (No of hard drives)}$$

$$n_3 = 3 \text{ (No of memory sticks)}$$

$$n_4 = 5 \text{ (No of accessory bundles)}$$

$$\square \text{Total number of ways} = n_1 \times n_2 \times n_3 \times n_4 = 2 \times 4 \times 3 \times 5 = 120$$

# Permutation

**Permutation:** A **permutation** is an arrangement of all or part of a set of objects.

OR

An arrangement of a set of  **$n$  objects** in a **given order** is called a ***permutation*** of the objects (taken all at a **time**).

**Example:** Consider the three **letters  $a$ ,  $b$ , and  $c$** .

The possible **permutations** are  **$abc$ ,  $acb$ ,  $bac$ ,  $bca$ ,  $cab$ , and  $cba$** .

# Permutation

□ **Definition** For any **non-negative integer  $n$** ,  $n!$ , called “ **$n$  factorial**,” is defined as  $n! = n(n - 1) \cdots (2)(1)$ , with special case  $0! = 1$ .

□ **Theorem 2.1:** The number of permutations of  $n$  objects is  $n!$ .

□ **Example** The number of permutations of the **four** letters  $a, b, c$ , and  $d$  will be  $4! = 24$ .

# Why 0! one?

The idea of the factorial (in simple terms) is used to compute the number of permutations (combinations) of arranging a set of **n numbers**.

n	Number of permutations (n!)	Visual examples
1	1	{1}
2	2	{1, 2}, {2, 1}
3	6	{1, 2, 3}, {1, 3, 2}, {2, 1, 3}, {2, 3, 1}, {3, 1, 2}, {3, 2, 1}
⋮	⋮	⋮
0	1	{ }

# Why 0! one?

$$n! = n \times (n - 1)!$$

$$\Rightarrow (n - 1)! = \frac{n!}{n}$$

Substitute 1, we get

$$\Rightarrow (1 - 1)! = \frac{1!}{1}$$

$$\Rightarrow 0! = 1$$

# Permutations Rule (When items are all different)

□ **Theorem 2.2:** The number of permutations of  **$n$**  distinct objects taken  **$r$**  at a time is  ${}_nP_r = \frac{n!}{(n-r)!}$ , where  **$r \leq n$**

# Permutations Rule (When items are all different)

1. There are  $n$  *different* items available. (This rule **does not apply** if some of the items are identical to others.)
2. We **select  $r$**  of the  $n$  items (without replacement).
3. We consider **rearrangements** of the **same items** to be **different sequences**. (The permutation of  **$ABC$**  is different from  **$CBA$**  and is counted separately)

# Permutations Rule (When items are all different)

□ If the preceding **requirements are satisfied**, the number of **permutations (or sequences)** of  **$r$  items** selected from  **$n$  different** available items **(without replacement)** is  ${}_nP_r = \frac{n!}{(n-r)!}$ , where  **$r \leq n$** .

**Example :** In one year, **three awards (research, teaching, and service)** will be given to a class of **25** graduate students in a statistics department. If each student can receive at **most one award**, how many possible selections are there?

**Solution :** Since the awards are **distinguishable**, it is a permutation problem. The total number of sample points is

$${}_{25}P_3 = \frac{25!}{(25-3)!} = \frac{25!}{22!} = (25)(24)(23) = 13,800.$$

**Example Clinical Trial of New Drug** When testing a new drug, Phase I involves **only 8 volunteers**, and the objective is to assess the drug's safety. To be very cautious, you plan to treat the **8 subjects in sequence**, so that any particularly adverse effect can allow for stopping the treatments before any other subjects are treated. If **10 volunteers** are available and **8 of them are to be selected**, how **many different sequences of 8 subjects** are possible?

**Solution** We have  $n = 10$  different subjects available, and we plan to select  $r = 8$  of them **without replacement**. The number of different sequences of arrangements is found as shown

$${}_{10}P_8 = \frac{10!}{(10 - 8)!} = \frac{10!}{2!} = 1,814,400$$

**Example** Find the number of ways of forming four-digit codes in which no digit is repeated.

## Solution

To form a four-digit code with no repeating digits, you need to select 4 digits from a group of 10, so  $n = 10$  and  $r = 4$ .

$${}_{10}P_4 = \frac{10!}{(10-4)!} = \frac{10!}{6!} = 5040$$

So, there are **5040** possible four-digit codes that do not have repeating digits.

**Example** How many 4-digit numbers are there with no digit repeated?

## Solution

$$\begin{aligned}\text{Total number of ways} &= 9 \times 9 \times 8 \times 7 \\ &= 4536\end{aligned}$$

**Example Forty-three** race cars started the **2013 Daytona 500**. How many ways can the cars finish first, second, and third?

## Solution

You need to select three race cars from a group of 43, so  $n = 43$  and  $r = 3$ . Because the order is important, the number of ways the cars can finish first, second, and third is

$${}_{43}P_3 = \frac{43!}{(43 - 3)!} = \frac{43!}{40!} = 74,046.$$

**Theorem 2.3:** The number of **permutations** of  $n$  **objects** arranged in a circle is  $(n - 1)!$ .

**Example** In how many ways can **6 people** be seated at a **round table**?

**Solution**

**Here  $n = 6$**  (total number of people)

The total number of ways =  $(6 - 1)! = 120$

**Example** Find the number of ways in which **5 people A, B, C, D, E** can be seated at **a round table**, such that

- a. A and B** must always sit together.
- b. C and D** must not sit together.

❑ **Solution a.** If we wish to seat **A and B** together in all arrangements, we can consider these **two as one unit**, along with 3 **others**. So effectively we've to arrange **4 people** in a circle. The number of ways =  **$(4 - 1)! = 6$**

But in each of these arrangements, **A** and **B** can themselves interchange places in **2 ways**.

Therefore, the total number of ways will be  **$6 \times 2 = 12$** .

## 5 people A, B, C, D, E

- ❑ **b.** The total number of ways will be  $(5 - 1)!$  or **24**.
- ❑ Similar to **a.** above, the number of cases in which **C** and **D** are seated together, will be **12**.
- ❑ Therefore the required number of ways = **24 - 12 = 12**.

# Permutations when repetition is allowed

- ❑ So far we have considered **permutations** of **distinct objects**. That is, all the objects were completely different or distinguishable.
- ❑ Obviously, if the letters **b** and **c** are both equal to **x**, then the **6 permutations** of the letters **a, b, and c** become **axx, axx, xax, xax, xxa, and xxa**, of which only **3** are distinct.
- ❑ Therefore, with **3 letters, 2 being the same**, we have  **$3!/2! = 3$**  distinct permutations.

# Permutations Rule (When some items are identical to others)

□ **Theorem 2.4:** The number of **distinct permutations** of  **$n$  things** of which  **$n_1$**  are of one kind,  **$n_2$**  of a second kind, . . . ,  **$n_k$**  of a  **$k^{\text{th}}$**  kind is

$$\frac{n!}{n_1!n_2! \cdots n_k!}$$

**where  $n_1 + n_2 + n_3 + \dots + n_k = n$ .**

# Permutations Rule (When some items are identical to others)

## Requirements

1. There are  $n$  items available, and some items are identical to others.
2. We select all of the  $n$  items (without replacement).
3. We consider rearrangements of distinct items to be different sequences.

If the preceding requirements are satisfied, and if there are  $n_1$  alike,  $n_2$  alike,  $\dots$ ,  $n_k$  alike, the number

$$\frac{n!}{n_1!n_2! \cdots n_k!}$$

**Example** A building contractor is planning to develop a subdivision. The subdivision is to consist of **6 one-story houses**, **4 two-story houses**, and **2 split-level houses**. In how many **distinguishable** ways can the houses be arranged?

## Solution

The total number of arrangements =  $\frac{12!}{6! 4! 2!}$

$$= 13,860$$

distinguishable ways

**Example** Calculate the number of distinguishable permutations of the letters **AAAABBC**.

## Solution

The total number of arrangements =  $\frac{7!}{4! 2! 1!}$

$$= 105$$

distinguishable ways

□ **Example** In a college football training session, the defensive coordinator needs to have **10 players** standing in a row. Among these **10 players**, there are **1 freshman**, **2 sophomores**, **4 juniors**, and **3 seniors**. How many **different ways** can they be arranged in a row if only their **class level** will be distinguished?

## □ Solution

$n = 10$  (Total number of players)

$n_1 = 1$  (Total number of freshman)

$n_2 = 2$  (Total number of sophomores)

$n_3 = 4$  (Total number of juniors)

$n_4 = 3$  (Total number of seniors)

$$\begin{aligned}\text{The total number of arrangements} &= \frac{10!}{1! 2! 4! 3!} \\ &= 12,600.\end{aligned}$$

**Theorem 2.5:** The number of ways of **partitioning** a set of  **$n$  objects** into  **$r$  cells** with  **$n_1$  elements** in the first cell,  **$n_2$  elements** in the second, and so forth, is

$$\binom{n}{n_1, n_2, \dots, n_r} = \frac{n!}{n_1! n_2! \cdots n_r!}$$

where  **$n_1 + n_2 + \cdots + n_r = n$**

**Example :** In how many ways can **7 graduate** students be assigned to **1 triple** and **2 double** hotel rooms during a conference?

***Solution :***

$$\frac{n!}{n_1!n_2! \cdots n_k!}$$

**Here  $n = 7$**

$$n_1 = 3$$

$$n_2 = 2$$

$$n_3 = 2$$

The total number of possible partitions would be

$$\frac{7!}{3! 2! 2!} = 210$$

**Theorem 2.6:** The number of combinations of ***n*** distinct objects taken ***r*** at a time is

$${}_nC_r = \frac{n!}{r!(n-r)!}, \text{ where } r \leq n.$$

# Combinations Rule

## Requirements

1. There are ***n different*** items available.
2. We select ***r*** of the ***n items*** (**without replacement**).
3. We consider rearrangements of the **same items** to **be the same**. (The combination ***ABC*** is the same as ***CBA***.)

If the preceding requirements are satisfied, the number of **combinations** of ***r items*** selected from ***n different items*** is

$${}_nC_r = \frac{n!}{r!(n-r)!}$$

# Combination vs. Permutations

❑ The **2-permutations** of the letters **A, B, C, and D** are:

**AB, AC, AD, BA, BC, BD, CA, CB, CD, DA, DB, DC.**

❑ The combinations of two out of these four letters are:

**AB, AC, AD, BC, BD, CD.**

(Since the elements of a combination are unordered, **BA** is not viewed as being distinct from **AB**.)

□ **Example:** In a lottery, each ticket has **5 one-digit numbers 0-9** on it.

a) You win if your ticket has the **digits in any order**. What are your chances of winning?

b) You would win only if your ticket has the digits in **the required order**. What are your chances of winning?

Solution:

There are 10 digits to be taken 5 at a time.

a) The number of ways of **selecting 5** tickets **from 10** is

$${}_{10}C_5 = \frac{10!}{5!(10-5)!} = \frac{10 \times 9 \times 8 \times 7 \times 6}{5!} = 252$$

∴ The chances of winning are **1 out of 252 (0.0040 or 0.3968 %**

□b) Since the order matters, we should use permutation instead of combination.

$${}_{10}P_5 = \frac{10!}{(10-5)!} = \frac{10!}{5!} = 10 \times 9 \times 8 \times 7 \times 6 = \mathbf{30240}$$

∴ The chances of winning are 1 out of 30240  
(**0.0000330668** or **0.0033 %**)
